

Why 16-25 age group has higher accident rate?

Neuroscience studies indicate that individuals aged 16 to 25 go through a developmental stage in which the prefrontal cortex continues to mature. This brain region is responsible for executive functions such as planning, impulse control, risk assessment, and decision-making. At the same time, the brain's reward and emotional

systems tend to be more active, creating a temporary imbalance between the desire for immediate rewards and the ability to regulate behavior. This interaction is believed to contribute to a greater tendency toward risk-taking behaviors, such as excessive speeding and impulsive driving. It is considered one of the factors that may help explain the higher rates of road accidents among young people, along with other factors such as limited driving experience and environmental and social conditions.

How mitigate the high accident rates among the 16–25 age group?

Ban Peer Passengers: Restrict young passengers for novice drivers to cut out social distraction and risk-taking.

Enforce Night Curfews: Limit unsupervised driving during high-risk late-night hours (e.g., 11 PM to 5 AM).

Use Telematics: Track driving behavior via apps and reward safe driving with lower insurance costs.

Vehicle Speed Caps: Use car tech (like smart keys) to limit maximum vehicle speed.
